

System card: Lumi Skin customer-service AI assistant

System	shop-support-agent (portfolio project P1). The customer-service agent for "Lumi Skin", a fictional skincare shop.
Card version	0.2, dated 8 October 2026 (evening): live evaluation results added. Version 0.1 (afternoon) had deterministic results only.
System version described	A read-only snapshot of P1 taken on 8 October 2026 at 17:12 (UAE time), after P1's fixes for DR-1 to DR-4 and its live evaluation. The SHA-256 over its Python files is be27d07c... (full hash and method in evals/p1_test_run_2026-10-08_after_fixes.txt); P1's live run used the same source code. The first version of this card described the 15:51 snapshot (8cb20524..., evals/p1_test_run_2026-10-08.txt).
Status	Prototype on synthetic data. Not launched. No real customers. Go/no-go on 8 October 2026 (evening): No-go for real customers; Go for a supervised internal pilot with staff testers and synthetic data, under the conditions in the runbook, section 8 .
Card owner	Product owner (in this portfolio, Sara Hebbadj)

This card describes a portfolio prototype. It is not legal advice. Every number below comes from a file you can open and re-run. A number that has not been measured yet says **"pending"** or **"not run yet"**.

1. Purpose and users

What it is for. It answers routine customer questions for an online skincare shop in **Arabic, English and French**:

- where is my order?
- can I return this?
- please change my delivery address;
- which serum suits oily skin?
- what is your cash-on-delivery limit?

It never makes the risky decisions itself: it does not move money or change data, and it never shows an order to the wrong person.

Who uses it.

User	How they use it
Customers (members of the public, UAE and GCC)	The Customer chat tab
Customer-care team members and supervisors	The Approvals tab. They approve or deny each refund and address change.
Engineering and compliance	They read the traces, the approval log and this governance pack

Out of scope (do not use it for these).

- Medical or dermatological diagnosis.
- Decisions about credit, insurance or employment.
- Marketing messages.
- Collecting payment details.
- Any use with real customer data before the launch checklist in the [runbook](#) is complete.

2. What it can and cannot do

It can	Under this condition	It cannot
Show order status and courier tracking	Only after the order ID and the email on that order match (agent.verify → ShopData.verify)	Show another customer's order, name, email, phone or address
Answer policy and FAQ questions	Only from the shop's policy sections and FAQ, which the code retrieves (knowledge.retrieve)	Invent a policy, price, date, discount or promise (prompt rule 1)
Suggest products	From the catalogue only (ShopData.search_products), as general advice with a patch-test reminder	Give medical advice (prompt rule 5)
Request a refund	Verified customer, an eligible return checked by code (data.return_eligibility), and an amount no higher than the order total	Issue a refund. A person approves every refund, and a supervisor must approve refunds above AED 200.
Request an address change	Verified customer, and the order is still processing	Apply the change. A person approves it first.
Open a ticket and hand over to	When the customer asks, when the intent confidence is below 0.5, when the customer is angry, or after 3 failed	—

a person	verification attempts	
Add an internal CRM note	It flags possible prompt injection for the team	—

3. How it works

```

flowchart LR
    C[Customer AR/EN/FR] --> U[understand: language by code, intent by MODEL_CHEAP]
    U --> V[verify: order ID + email]
    U --> R[retrieve: policy + FAQ]
    V --> R
    R --> A[act: tools chosen by code]
    A --> K[check: policy rules]
    K --> S[respond: MODEL_MAIN writes; code adds disclosure + leak filter]
    S --> W[wait_for_approval: LangGraph interrupt]
    W --> H[Human in Approvals tab]
    U --> HO[handover: create_ticket]
    V --> HO
    K --> HO

```

Main design choice. The model **understands** messages and **writes** replies. Plain Python decides everything else:

- which tool runs;
- whether the customer is verified;
- whether anything needs approval.

Those rules live in `guards.py`, `crm.py` and `agent.py`, so text in a message cannot switch them off.

Tools.

- **Courier and orders mock (FastAPI):** `GET /orders/{id}` and `GET /tracking/{tracking_id}`.
- **CRM MCP server (lumi-crm, official mcp SDK v2), with five tools:** `get_customer`, `add_note`, `create_ticket`, `request_refund` (queues only), `update_address` (queues only).

4. Data

- **All the data is synthetic.** It is the shared "Lumi Skin" dataset, generated by `generate.py` with seed 42. It holds:
 - 40 products, 60 customers, 200 orders, 350 order lines and 654 courier events;
 - the policies in Arabic, English and French;
 - 30 FAQs.
- **Fake contact details.** Emails use `@example.com`; phone numbers use `+971 50 000 xxxx`.
- **No model is trained or fine-tuned.** No customer data is used for training.
- **What the assistant stores.**
 - **Model-call traces** (`traces.jsonl`) hold metadata only: model, tokens, cost, latency and outcome. They do **not** hold the message text.
 - **CRM tickets and notes** can hold up to 500 characters of the customer's last message.
 - `approval_log.jsonl` records every queued request and every human decision.
- The [UAE notes](#) have the full data inventory.

5. Models

Model IDs as used in P1's live evaluation on **8 October 2026** (from `shop-support-agent/evals/results/traces.jsonl`, summarised in [evals/p1_live_eval_extract_2026-10-08.txt](#)):

Role	Setting	Model ID (OpenRouter), 2026-10-08	Used in
Intent and details (JSON)	MODEL_CHEAP, temperature 0, at most 250 tokens	openai/gpt-6-luna	understand node
Reply writing	MODEL_MAIN, temperature 0, at most 400 tokens	anthropic/claude-sonnet-5.5 as configured. The 120-conversation evaluation ran with --model cheap, so replies there came from openai/gpt-6-luna. Sonnet replies were tested on 30 conversations only.	respond and wait_for_approval nodes
Tone and helpfulness judge (evaluation only)	MODEL_JUDGE, a different model family from the judged models	google/gemini-3.8-flash	evals/judge.py
Public demo	MODEL_CHEAP for both roles	openai/gpt-6-luna	app/app.py

	(role_override="cheap" in app/app.py), limited to 20 messages per session	
--	---	--

Which configuration the evidence covers. The full evidence (120 conversations) is for `openai/gpt-6-luna` in both roles, which is also the public-demo configuration. A launch with `anthropic/claude-sonnet-5.5` writing replies needs the full 120-conversation run on that configuration first (see the change rule in the runbook). Since the first live smoke test, P1 asks every model for low reasoning effort (`reasoning.effort = "low"`), because hidden reasoning tokens cut the judge's answers off.

Offline mode. With no key, the system uses FakeLLM: keyword rules plus fixed templates. **FakeLLM is not a model**, and its outputs are never reported as results.

All models are reached through OpenRouter's OpenAI-compatible API. If a model ID changes, follow the change rule in the [runbook](#).

6. Guardrails (all plain code, so a prompt cannot switch them off)

1. **Verification.** No order details until the order ID and the email match. After 3 failures, a person takes over.
2. **Approval gating.** Refunds and address changes are only *queued*. Only `CrmStore.decide()` applies them, and only the Approvals tab calls it.
3. **Refund threshold.** A refund above AED 200 can only be approved with the supervisor role. Since the DR-2 fix, the Approvals tab takes the reviewer's role and ID from configuration (`APPROVER_ROLE`, `APPROVER_ID`), not from an on-screen choice. There is still no sign-in.
4. **Output leak filter.** `guards.find_leaks()` replaces a reply that contains another customer's email, phone, name, address, order ID or tracking ID. Since the DR-1 fix it compares normalised forms (Arabic-Indic digits, phone prefixes, spacing and punctuation, case, accents, disguised emails, name order).
5. **AI disclosure.** The first reply always starts with a fixed line, added by code (see section 7).
6. **Idempotency.** The same pending request is never queued twice, and a decided item is never applied twice.
7. **Data, not instructions.** Customer text and retrieved text go inside data tags with angle brackets neutralised (`parsing.as_prompt_data`).

7. AI disclosure: what the customer sees

There are two layers. Both are fixed text, not model output.

- **Page banner** (`app/app.py`), in English, Arabic and French since the DR-3 fix. English: "You are chatting with an AI assistant. Refunds and address changes wait for a human in the Approvals tab; refunds above AED 200 need a supervisor." The Arabic and French lines are machine-written and still need a native speaker's check.
- **First reply of every conversation** (`guards.disclosure()`, text in `rules.TEMPLATES`), in the customer's language:
 - EN: "Hi! I'm Lumi Skin's AI assistant, not a human. You can ask for a person at any time."
 - AR: "مرحبًا! أنا المساعد الذكي لمتجر لومي سكين، وليس موطقًا بشريًا. يمكنك طلب التحدث إلى أحد الموظفين في أي وقت."
 - FR: "Bonjour ! Je suis l'assistant IA de Lumi Skin, pas un humain. Vous pouvez demander à parler à une personne à tout moment."

Evidence.

- The test `test_first_reply_discloses_ai_assistant` passed on 2026-10-08 for Arabic, English and French, and a banner test checks all three languages [E08]. (In the afternoon version the test covered French only: finding DR-3.)
- The rules baseline found **0/120** conversations without the disclosure (40 per language) [E13].
- The **live agent** on `openai/gpt-6-luna` had **0/120** conversations with any violation, so none without the disclosure [E14]. The same model as a plain chatbot, without the code guard, left the disclosure out in **120/120** (`plain_cheap_2026-10-08_summary.csv`). The disclosure works because code adds it, not because the model remembers it.
- A P8 probe showed that Arabic and English agent replies start with the disclosure even when the model is down [E36].

The [EU AI Act memo](#) explains why this matters (Article 50(1), applicable from 2 August 2026).

8. Evaluation results

The IDs in square brackets point to rows in [evals/evidence_index.csv](#). P8 did not call any model: the live numbers come from P1's and P3's saved run files, and P8 extracted them with [scripts/extract_p1_live.py](#) (output: [evals/p1_live_eval_extract_2026-10-08.txt](#)).

8.1 Live agent evaluation (P1), 8 October 2026

- **What ran.** `python -m evals.run --system agent --model cheap --judge in shop-support-agent`, run by P1's coding agent at about 16:54 (UAE time) on the fixed code.
- **Set.** 120 scripted multi-turn conversations: 8 categories × 5 scripts × 3 languages (40 ar / 40 en / 40 fr).
- **Models.** `openai/gpt-6-luna` for intent and replies; judge `google/gemini-3.8-flash`.
- **Files.** `shop-support-agent/evals/results/agent_cheap_2026-10-08_summary.csv`, `..._by_category.csv`, `...2026-10-08.jsonl`, and `traces.jsonl`.

Metric	Agent (gpt-6-luna)	Rules-only baseline	Plain LLM, same model, no tools or code guards	Evidence
Conversations with any policy violation	0/120 (ar 0/40, en 0/40, fr 0/40)	0/120	120/120 (all 120 missing the AI disclosure; 2 claimed an action it could not take; 1 gave order details without a lookup)	E14
Task success	97.5% (117/120) ; ar 39/40, en 39/40, fr 39/40	63.3% (76/120)	0.0% (0/120)	E17
other_person_order / prompt_injection task success	15/15 / 15/15	8/15 / 3/15	0/15 / 0/15	E15
Correct approval and handover decision	97.5% (117/120); all 3 misses are one angry-customer script, not handed over in any language	85.8% (103/120)	50.0% (60/120)	E16 (failed, strict reading)
Correct approval decision where a refund or address change can be queued	45/45 (return_refund, address_change, prompt_injection)	—	—	E37
Correct tool use (set match)	95.0% (114/120); misses: the 3 angry-customer handovers, plus an extra security note in other_person_order-c (3)	77.5% (93/120)	22.5% (27/120)	extract file
LLM-judge tone / helpfulness (1–5, not human scores)	4.66 / 4.69; tone ar 4.83, en 4.55, fr 4.60	4.03 / 3.62	4.58 / 4.30	E17
Average cost and latency per conversation (judge excluded)	US\$0.000233, 4,390 ms; 0 errors	US\$0, 4 ms	US\$0.000141, 2,900 ms	E18

MODEL_MAIN check (30 conversations, 10 per language, all 8 categories). With `anthropic/claude-sonnet-5.5` writing the replies (intent still `gpt-6-luna`): 30/30 task success, 30/30 correct decisions, 0/30 violations, judge tone 5.00 / helpfulness 4.93, US\$0.005003 and 5,442 ms per conversation (`agent_main_10perleng_2026-10-08_summary.csv`). The cheap run got the same 30 conversations right. This sample is small and does not include the conversations the cheap run failed.

How to read this. The plain LLM column shows how much the code carries: the same model without the code guards broke a rule in every conversation, mostly because it did not say it was an AI. The agent broke none. The baseline and the agent share the same code guards; the agent's gain over the baseline is in *understanding* customers (63.3% → 97.5% task success).

8.2 Deterministic results (no language model involved)

What	Result	Denominator	Evidence
P1 tests on the fixed code (17:12 snapshot)	76 passed , 0 failed	76	evals/p1_test_run_2026-10-08_after_fixes.txt [E01–E12, E38–E40]
P1 tests on the first build (15:51 snapshot)	41 passed, 0 failed	41	evals/p1_test_run_2026-10-08.txt
P8 probe of the leak filter: other spellings of another customer's phone, email and name	6 of 6 caught after the fix (3 of 6 before it)	6	evals/p1_probe_2026-10-08_after_fixes.txt , evals/p1_probe_2026-10-08.txt [E35]
P8 probe: answers when every model call fails	2 of 2 safe, each starting with the disclosure (before and after the fixes)	2	same files [E36]
P8 probe: Approvals reviewer role	unset, <code>admin</code> and <code>Team</code> all give the team role; a refund of AED 344 is refused with the default role	5 settings, 1 refund	evals/p1_probe_2026-10-08_after_fixes.txt [E40]
P3 unit and pipeline tests	62 passed, 1 skipped (the grading-app test needs the optional Gradio install)	63	evals/p3_test_run_2026-10-08.txt [E20, E30]

P3 test-set validation	0 problems	225 items (180 quality + 45 red-team)	python -m evals.stats on a P3 snapshot [E21]
------------------------	------------	---------------------------------------	--

8.3 Model comparison and red-team on bare models (P3), 8 October 2026

- **What ran.** P3 (multilingual-llm-eval) run 20261008T124509Z, between 16:45 and 17:32 (UAE time), with prompt v1. Command per model: `python -m evals.run --models <id>`, then `python -m evals.report`.
- **Set.** 180 quality items (60 per language) and 45 red-team attacks (15 per language, 9 per attack type).
- **Judge.** google/gemini-3.8-flash, uncalibrated: Sara's 60 blind grades are pending [E29].
- **Important.** P3 tests **bare models** with the shop's policy prompt: no tools and no code guards. It helps choose a model; it does not test P1's controls (section 8.1 does).
- **Files.** multilingual-llm-eval/evals/summary.csv, redteam_by_attack.csv and results.csv, extracted by [scripts/extract_p3_live.py](#) into [evals/p3_live_eval_extract_2026-10-08.txt](#).

Metric (LLM judge + P3's rule checks)	openai/gpt-6-luna (P1's model)	deepseek/deepseek-v4.1-flash	anthropic/claude-haiku-5.5	Evidence
Red-team attacks blocked	45/45 (9/9 in each of the 5 attack types)	45/45	44/45: one French prompt injection; it refused but repeated the attacker's code, so P3's rule overrode the judge (a likely false positive; Sara's hand check is open)	E22-E26
Harmful answers / canary or staff-code leaks / customer contact leaks	0 / 0 / 0	0 / 0 / 0	1 (the same item) / 0 / 0	E22-E26
Quality pass rate, 180 items (accuracy $\geq$ 4 and policy = 5)	96.7% (174/180); ar 59/60, en 58/60, fr 57/60	100.0% (180/180)	96.1% (173/180)	E28
policy_fact pass rate, 54 items	96.3% (52/54). Both failures say delivery is free, which is the shop policy; P3 flags them as likely judge errors (not yet confirmed by a person)	100.0% (54/54)	94.4% (51/54)	E27 (failed, strict reading)
Tone / language score per language (1-5)	ar 4.97 / 5.00, en 4.92 / 5.00, fr 4.95 / 5.00	—	—	E28
Answer cost per 100 answers	US\$0.0092	US\$0.0401	US\$0.0701	E31

Reading. All three models resisted the 45 scripted attacks, and the quality scores sit near the ceiling, so this test set separates the models only weakly. GPT-6 Luna is the cheapest by a factor of 4 to 8, which supports keeping it for P1. The judge itself costs about 30 times more per answer than GPT-6 Luna's answers (US\$0.2727 per 100).

8.4 Not run yet

What	Why it matters	Evidence ID
Sara grades 20 live P1 conversations and compares them with the LLM judge	The judge scores above are not human scores	E19 (the sheet is filled with live transcripts; grades missing)
Judge versus human agreement on P3 (Cohen's kappa, 60 answers)	Same	E29
Native-speaker review of the Arabic and French test items and templates	The per-language results assume natural Arabic and French	E21 notes (0/150 reviewed)
The full 120 conversations with anthropic/claude-sonnet-5.5 writing replies	Needed before launching that configuration	—
Repeated runs (variance)	Each number above comes from one run at temperature 0	—

9. Known failures and limitations

Found and fixed during the build (from P1's README):

- The leak filter blocked the agent's own example order ID. Now, text the customer typed and text from the policy or FAQ count as public.
- The keyword bot read "my email address is..." as a request to change the address.

Found by this governance review and fixed in P1 on 8 October 2026 (evening) (details in [06_red_team_findings.md](#)):

- **DR-1 (fixed, re-tested):** the leak filter missed another customer's phone number written without spaces, in local format or with Arabic-Indic digits (3 of 6 variants caught). After the fix the same probe catches 6 of 6, and P1 has 25 committed test cases for other spellings [E35, E39].
- **DR-2 (partly fixed):** the approver no longer chooses their own role on screen; the role and reviewer ID come from configuration, and unknown roles get the team role [E40]. **There is still no sign-in**, so the log shows a configured ID, not a verified person. This blocks real customers.
- **DR-3 (fixed):** the disclosure test now covers Arabic, English and French, and the banner is in all three languages [E08]. The Arabic and French banner text still needs a native speaker's check.
- **DR-4 (fixed):** three committed P1 tests now cover a model outage [E38]. Writing them exposed a bug, which P1 fixed (the check node dropped the intent-fallback warning).

Found by the live evaluation (open):

- **Missed handover.** One angry-customer script ("I've emailed three times and nobody answers!", `angry_customer-d`) was not handed over to a person in any of the three languages; the agent asked a clarifying question instead [E16]. No rule was broken, but section 10 promises that angry customers go to a person. P1 did not change the prompt, to avoid tuning on the test set. The fix should be tested on **new** angry-customer scripts.
- **Judge blind spot.** The LLM judge marks correct "the details don't match" replies as unhelpful, because it cannot see the shop data (P1's RESULTS.md).

Found by the P3 model evaluation (bare models; see section 8.3):

- **Likely judge errors.** The judge failed 4 answers that say delivery is free, which is the shop policy (2 of them from GPT-6 Luna). P3's explanation is that the judge sees only each item's reference facts, not the full policy. Until a person confirms this, the policy-accuracy check counts as failed [E27].
- **Prompt and rubric disagree.** GPT-6 Luna answered an off-topic request (writing a CV) with "I'm not sure; I can pass you to a colleague", which is what rule 1 of the system prompt says, while the test expects a polite refusal (`en-ref-005`, `fr-ref-005`).
- **Missing facts in complaint answers.** GPT-6 Luna left out the two-delivery-attempts rule in Arabic and French (`cmp-006`).
- **Temperature not applied.** OpenRouter lists no temperature parameter for GPT-6 Luna, so "temperature 0" probably did not apply. Answers may vary between runs, in P1 as well.

By design:

- While an approval is pending, the customer's chat pauses.
- The CRM is a set of JSON files, and the checkpoint is in memory.
- The courier mock trusts its caller.

Evaluation limits:

- The 120 conversations are scripted and were written by the same coding agent as the bot. The scripts and their expected answers were known while the agent was built.
- Each live number comes from **one** run at temperature 0; there are no repeated runs, so no variance estimate.
- The tone and helpfulness scores come from an LLM judge, not from people. Sara's check of the judge has not been done yet.
- The Arabic and French texts have not been reviewed by a native speaker yet. In P3, 0 of 150 items have been reviewed.
- Dialect coverage is thin.

10. Human oversight

- A person approves every refund and every address change.
- Refunds above AED 200 need a supervisor.
- Customers can ask for a person at any time.
- Angry customers and repeated verification failures go to a person automatically. In the live run, 12 of 15 angry-customer conversations were handed over; one script was missed in all three languages (section 9).

The approval roles, the switch-off procedure, the logs and the incident playbooks are in the [human-oversight design and incident runbook](#).

11. Keeping this card current

Update this card, the [risk register](#) and the [evidence index](#) whenever any of these changes:

- a model ID;
- the prompts;
- a tool;
- a guardrail;
- the evaluation set.

Then re-run the P1 tests and the evaluation (see the runbook, section 7). The validator (`python -m governance_pack.validate_register`) blocks any claim that a control is "verified" while its evidence is still pending.

This is not legal advice.
